Cotton Defoliation

Defoliation is the shedding of cotton leaves that naturally occurs when leaves become physiologically mature. Leaf shedding (abscission) results from activity of special cells at the base of the leaf petiole where it joins the stem. This area is called the “abscission layer.” Defoliation may also be induced by a light frost, insect damage, disease, drought or mineral deficiency. It also can be artificially achieved by the use of certain chemicals called “defoliant” or harvest aids. **In situations where canopies are dense and there are significant numbers of green bolls that need to be opened, two applications are often required.** Planning a two-pass approach, especially in lush, irrigated cotton, as opposed to getting less-than-desirable results such as stuck leaves or poor defoliation from a single application attempt is recommended. The goal of the first application is to remove as much foliage as possible exposing the unopened bolls without causing desiccation. The second harvest aid application will require additional defoliant to finish removing lower canopy leaves but, more importantly, an adequate boll opener to stimulate boll opening.

Desiccation is drying of plant tissues due to disruption of cell membranes and rapid loss of moisture which often results in “stuck leaves.” Product selection and application rates should be adjusted to match environmental conditions as they change during the harvest season in order to reduce occurrence of leaf desiccation.

What Are the Benefits From Defoliation?

- Removes leaves.
- Eliminates the main source of stain and trash.
- Better lint grades.
- Prevents boll rot.
- Faster and more efficient picker operation.
- Manages maturity, allowing earlier harvest.

- Increases air movement through the crop canopy which facilitates quicker drying, thus allowing picker to begin earlier in the day.
- Reduces moisture.
- Improves storage in modules.

Application Timing and Conditions

Weather – Weather conditions at the time of application and three to five days following application have a significant effect on cotton response to harvest aids. Harvest aids are most active when temperature, sunlight intensity and relative humidity are high. Night-time temperatures above 60°F are especially important with regard to activity of certain harvest aids. At temperatures above 60°F, the rate of leaf drop roughly doubles for each 10° rise in temperature. At least one full day of clear weather following application is needed for best results.

Plant Conditions – Defoliation is best in mature, well-fruited, uniform plants that have “cutout” but are not completely inactive. Plant nutrient supply, particularly nitrogen, should be almost exhausted, and the crop should not be under drought stress. Poor defoliation may result when defoliants are applied to drought-stressed crops which may have leaves with thick cuticles.

Application Timing – There are many ways to determine proper defoliation timing, but the following have proven to be effective:

- **NAWF 5 + 850 DD60s:** Using heat unit accumulation after NAWF (node above white flower) 5 has some merit when determining defoliation timing. Calculating DD60s after “cutout,” which is defined as the point where the cotton reaches NAWF=5, is a good way to gauge crop maturity; however, this method should be used in combination with other techniques. This method is almost certainly the first to recommend defoliation and can sometimes

trigger defoliation applications too early. DD60 accumulation after NAWF=5 should always be accompanied by determination of percent open bolls and visual inspection to ensure that premature defoliation does not occur. Early defoliation can reduce micronaire and has also been shown to reduce yield in some situations. One must first weigh the benefits of decreased micronaire vs. the potential yield loss from early defoliation.

- **Percent Open Boll:** Measuring percent open boll has been the standard defoliation technique for many years and is still the “old standby.” It is generally safe to defoliate when 60 percent of the bolls are open. However, this strategy may not work well in situations where fruit has been set over a varying period of time due to plant stresses such as insect damage. In some situations, defoliation at 60 percent open may be premature and cut short the development of bolls in the upper canopy, thereby reducing yield and micronaire. On the other hand, a crop set in a short period of time could be safely defoliated at 40 to 50 percent open boll. Many producers tend to underestimate percent open boll and may actually be waiting until 70 to 80 percent open to defoliate. Estimating percent open boll from the truck will generally underestimate percent open bolls. To accurately determine percent open bolls, measure 3 feet of row in 10 places in the field and actually count open and closed bolls and calculate the percent that are open.
- **Node Above Cracked Boll (NACB):** To use the NACB method, find the uppermost first position cracked boll and count upwards on the plant to the uppermost harvestable boll. Once NACB has been determined, cut the uppermost harvestable boll with a sharp knife to inspect the lint and seed. If the boll is mature, then defoliation is safe. A NACB of 4 is generally safe for defoliation. If the uppermost harvestable boll is immature, wait until NACB of 3. In addition, low plant populations (less than two plants per foot of row) may require a NACB count of 3 to be safe. Low plant populations result in a less evenly distributed fruit load with high numbers of bolls set on vegetative branches and outer positions of fruiting branches.
- **Sharp Knife Technique:** The sharp knife technique should be used to validate all methods of defoliation timing. Choose the uppermost boll that has a chance of contributing to yield and make a cross section of the boll with a sharp knife. Generally this boll will be located 4 to 5 nodes below the terminal depending on end-of-season stresses. Bolls are mature when they are difficult to cut and a cross section of the seed reveals folded cotyledons, absence of jelly and darkened seed coats.

- **Hal Lewis Method:** The Hal Lewis Method of timing defoliation has gained momentum over the last several years and has shown promise in predicting end-of-season micronaire. The system uses a representative sample of the bottom four first position bolls and compares the micronaire to a chart which predicts whole field micronaire. If whole field micronaire is predicted to be in the discount range, defoliation prior to 60 to 70 percent open is recommended. The technique may save a producer from discounts while maintaining yields. For those producers interested in this method, see the web site <http://www.arkansascrops.com> for more information.

Regardless of which method you prefer, a combination of several techniques should always be used. All growers are urged to walk as many of their fields as possible and determine the overall maturity of their crop. Rarely do all portions of a field mature at the same time. Therefore, the risks of defoliating too early or late can be reduced by using a combination of the aforementioned techniques.

Application – Most harvest aid materials do not translocate or move very far within the plant. Therefore, application coverage is important. Hollow cone nozzles are superior to air-induction nozzles as they improve foliar coverage using ground application equipment. Two equally spaced hollow cone nozzles per row will give adequate coverage. Spray pressure, ground speed and nozzle size should be matched appropriately in order to apply the desired spray volume in accordance with label instructions. The amount of water used as a carrier in each defoliation application should not be lower than 5 gallons per acre for aerial applications and 15 gallons per acre by

ground. A second application of defoliant may be required for defoliation of rank cotton. Consult the product label for rates and other pertinent information.

Other Factors to Consider When Defoliating

Do not defoliate all cotton at one time. Defoliants should be applied 10 to 14 days prior to anticipated harvest date. Leaf drop should start in about 4 days and be complete in about 10 days. Rain 3 to 4 hours after application of a defoliant does not lessen the effectiveness of most chemicals with the exception of thidiazuron, which requires a 24-hour rain-free period.

Types of Defoliants

Defoliants can be categorized as having either herbicidal or hormonal activity. Folex®, Aim®, Display™, ET® and Sharpen™ are herbicidal-type defoliants that injure the plant, causing it to produce ethylene in response to the injury. Ethylene production promotes formation of an abscission layer and ultimately leaf drop. Increased application rates of these materials during periods of warm temperatures may kill the leaf prior to ethylene synthesis. This results in desiccation or “leaf stick” instead of the desired defoliation (leaf drop).

Thidiazuron, Ginstar®, Finish® and ethephon are hormonal defoliants that result in increased ethylene synthesis by the plant. Ethephon releases ethylene, which stimulates further ethylene synthesis in the plant, resulting in abscission zone activation in the boll walls and leaf petioles. Thidiazuron contains a hormone known as a cytokinin. Although cytokinins promote leaf health in most plant species, in cotton very high concentrations of cytokinins promote ethylene synthesis and act as a defoliant. Because these hormonal-type defoliants bypass herbicidal injury, they are not as likely to cause desiccation (leaf stick) as herbicidal defoliants.

Herbicidal Defoliants

- **Folex®:** Phosphate-type materials containing tribufos (active ingredient in Folex®) have been used for years and are regarded as standards. Their performance is essentially equal, and they are effective over a broad range of environmental conditions. Minimum temperature for optimum performance is 55°-60°F. These materials do not inhibit regrowth or appreciably improve boll opening. Activity improves with increased maturity of the crop. Leaf removal with each of these products is usually rapid, and addition of surfactants offers benefit only under adverse conditions. These products have a pungent odor.

Labeled Rates: 16 – 24 oz per acre. Lower rates may be utilized in tank mixtures with other harvest aids.

- **Aim®:** Aim® (carfentrazone) has excellent activity for desiccation of juvenile growth but does not inhibit regrowth. In mature cotton and/or cool conditions, Aim® activity has been shown to be similar to Folex®. However, in warm conditions, less-than-desirable defoliation and excessive desiccation have been observed. In situations in which two applications are necessary, Aim® has performed very well as the second application. Aim® has shown excellent activity in desiccating morningglories. Aim® can be tank-mixed with any defoliant, and the addition of 1% v/v crop oil is needed.
Labeled Rates: 0.25 – 1.6 oz per acre.
- **Display™:** Display is a new cotton harvest aid that is a combination of the herbicides carfentrazone (Aim®) and fluthiacet-methyl (Cadet™). Similar to other herbicidal defoliants, Display™ has excellent activity on juvenile leaves including regrowth. However, Display™ will not inhibit regrowth. Under warm conditions, less-than-desirable defoliation and excessive desiccation may be observed. In situations in which two applications are necessary, Display™ has performed very well when included in the second application. Display™ has shown excellent activity in desiccating morningglories. In situations with thick vines, Display™ alone or in combination with other defoliants will desiccate morningglories very well. Addition of 1% v/v crop oil concentrate or 0.25% v/v NIS is needed.
Labeled Rates: 0.3 – 1.0 oz per acre.
- **ET®:** ET® (pyraflufen ethyl) has excellent activity for desiccation of juvenile growth but does not inhibit regrowth. In mature cotton and/or cool conditions, ET® activity has been shown to be similar to Folex®. However, in warm conditions, less-than-desirable defoliation and excessive desiccation have been shown with ET®. In situations in which two applications are necessary, ET® has performed very well as the second application. ET® can be tank-mixed with other defoliants, and the addition of 0.5 – 1.0% v/v crop oil is needed.
Labeled Rates: 1.5 – 2.75 oz per acre.
- **Sharpen:** Sharpen™ (saflufenacil) is a newly released herbicidal defoliant/desiccant. Sharpen™ has excellent activity on mature and juvenile leaves including regrowth. Sharpen™ will provide little to no inhibition of regrowth. During periods of warm to hot temperatures, application of Sharpen™ may lead to excessive desiccation. However, in a two-pass defoliation scenario, Sharpen™ has performed very well in the second application. Sharpen™

must be applied with methylated seed oil (MSO) at 1% v/v plus ammonium sulfate (AMS) or urea ammonium nitrate (UAN).

Labeled Rates: 1.0 – 2.0 oz per acre.

- **Glyphosate (many formulations):** Glyphosate provides excellent regrowth inhibition of conventional (non-Roundup Ready Flex™) cotton when applied in conjunction with defoliants or ethephon and helps control susceptible late-season weeds. Check specific product labels for registration as a harvest aide. Glyphosate will not enhance performance of harvest aids when applied to Roundup Ready Flex™ cotton.

Labeled Rates: 11 – 44 oz per acre Roundup WeatherMax™ or equivalent rate of alternative product for regrowth control in non-RR cotton.

Hormonal Defoliants and Boll-Opening Materials

- **Thidiazuron (many formulations):** Thidiazuron SC is formulated as a soluble concentrate, requires a 24-hour rain-free period and is sensitive to cool weather. Thidiazuron should not be applied when the average 24-hour temperature is predicted to be below 65°F for 2 to 3 days after application. In addition, thidiazuron products are slower with regard to leaf removal than Folex® and may leave some bottom leaves; however, they effectively remove juvenile foliage. Thidiazuron does not improve boll opening; however, it will strongly inhibit regrowth when applied under favorable weather conditions at appropriate use rates. The potential for leaf desiccation is reduced with thidiazuron compared to herbicidal defoliants, especially when applied during periods of high temperatures. If thidiazuron is applied under less-than-favorable conditions, the addition of crop oil concentrate may enhance the activity of these materials. It is important to follow suggested cleanout procedures with thidiazuron.

Labeled Rates: 1.6 – 6.4 oz/acre.

- **Ginstar®:** Ginstar® is an emulsifiable concentrate formulation of thidiazuron and diuron (Karmex®, Direx®). Ginstar® should be applied to mature cotton at least 5 days prior to scheduled harvest; however, defoliation may take longer under cool conditions. Addition of adjuvants or excess Ginstar® rates can cause desiccation or “stuck leaves” under warm conditions. The Ginstar® label does not discuss tank mixtures; however, tank mixtures with ethephon have enhanced boll-opening activity.

Labeled Rates: 6.4 – 16 oz per acre. Lower rates may be utilized during periods of extremely

warm air temperatures or in tank mixtures with other harvest aids.

- **Finish 6 Pro®:** Finish 6 Pro® contains ethephon and the synergist cyclanilide which aids in defoliation. Finish 6 Pro® is an excellent boll opener and may be used as a stand-alone product in warmer temperatures and well-cutout situations. Finish 6 Pro® exhibits a limited level of regrowth control and is generally a faster boll opener than ethephon. Finish 6 Pro® can be tank-mixed with thidiazuron, phosphate materials and Ginstar®.

Labeled Rates: 1.33 – 2.33 pints per acre.

- **Ethephon 6, BollBuster, etc.:** Ethephon is a boll-opening material that also enhances defoliation when applied in combination with other harvest aids. Acceptable defoliation with ethephon alone usually requires mature leaves, warm weather and high use rates. Ethephon does not help bolls mature but helps open mature and immature bolls. The addition of thidiazuron is recommended in cases where regrowth is expected.

Labeled Rates: 1.33 – 2.33 pints per acre.

Desiccants

- **Paraquat (Gramoxone SL™; Firestorm®):** Paraquat can aid in opening of mature bolls when 3.1 to 5 oz/A is applied in combination with Folex®, thidiazuron or ethephon. Development of immature bolls will be inhibited by paraquat application. Paraquat is not recommended for use as a defoliant or boll opener for spindle-picked cotton unless a freeze is imminent. Use higher rates for desiccation of weeds and for stripper-harvested cotton.

Labeled Rates: 3.1 – 32 oz per acre.

- **Sodium Chlorate (numerous brands available):** Higher rates of sodium chlorate may act as a desiccant, tending to stick leaves on the cotton plant. At normal use rates for defoliation, sodium chlorate is generally not as effective as the other defoliants. It is not a strong inhibitor of terminal growth. Do not mix the chlorates with phosphate defoliants, phosphate insecticides or Prep.

Defoliating Drought-Stressed and Rank Cotton

Drought-stressed cotton often has thick cuticles and leathery leaves that inhibit the uptake of many defoliants. The potential for regrowth is often high due to unused nitrogen remaining after premature cutout. Uptake of dry formulations of thidiazuron appears to be

slightly inhibited in drought-stressed cotton and higher rates and/or surfactants may be needed. Thidiazuron SC and Ginstar® are liquid formulations, and limited research suggests that their uptake may be less affected by drought-stressed cotton than dry formulations of thidiazuron. Tank mixtures with Folex®, as well as the addition of silicone surfactants or ammonium sulfate, have been shown to increase the uptake of thidiazuron in drought-stressed cotton. However, use caution when applying higher rates or adjuvants in warmer weather as desiccation and stuck leaves may result.

Obtaining adequate spray coverage makes defoliation of rank cotton challenging. A common mistake is to increase rates in an effort to achieve better defoliation. Increased rates are likely to cause leaf desiccation at the top of the plant where most spray solution is intercepted. The best approach is to apply normal rates and plan to make a second application. Rank cotton is generally more difficult to defoliate than normal cotton. However, if effective defoliation is achieved in the first application, the second application may not require high application rates of selected products or complex tank mixes. Additionally, a boll opener can be more effective if added to the second application due to increased coverage.

Drought-stressed cotton tends to have thicker cuticles that limit the penetration of some products. Addition of an approved adjuvant to hormonal-type harvest aid materials such as thidiazuron may improve defoliation when applied to drought-stressed cotton or when 60° to 65°F nighttime temperatures are expected. However, use of adjuvants with Ginstar® is not recommended due to increased likelihood of leaf desiccation, especially during periods of high temperatures. In addition, during high temperature situations, combinations of herbicidal-type defoliant may desiccate leaves. Regrowth is often a problem if rainfall occurs following application. Regrowth can be a concern with applications of Folex® alone or tank-mixed with ethephon, depending on moisture conditions and temperature following application. Activity of most defoliant is reduced under cooler conditions, at which time higher application rates will be needed. Regrowth is generally not as big a concern during periods of cooler weather compared to warmer weather. Boll openers should be added to all treatments to promote boll opening at least three but preferably five days in advance of freezing temperatures.

Rotational Crop Restrictions

Producers who wish to follow a cotton crop with a small grain such as wheat should observe the following re-crop intervals to prevent crop injury or stand failure.

Table 1. Label restrictions for planting small grains following harvest aid application in cotton.

Harvest Aid	Small Grain Re-Crop Interval
Thidiazuron®	14 days
Ginstar®	1 month
Folex® 6	None
Aim®	None
Display™	None
ET®	None
Sharpen®	None
Glyphosate	None
Finish® 6 Pro	1 month
Ethephon	30 days
Paraquat	None
Sodium Chlorate	None

Additional Questions

Additional questions regarding information contained within this guide may be directed to your local Extension specialist.

Disclaimer

Information contained within this publication is intended to serve as a guide with regard to cotton defoliation. Many factors influence activity of harvest aid materials. Leaf desiccation and stuck leaves may result with any harvest aid application. Use this guide and previous experience when selecting harvest aid programs.

Table 2. Use pattern and expected activity for defoliants and desiccants.

Harvest Aid ¹	Labeled Broadcast Rate/Acre	Max. Use Per Season	Rain-Free Period (hours) ²	Pre-Harvest Interval (days)	Estimated Min. Temp.	Mature Leaves	Juvenile Growth	Regrowth Prevention	Boll Opening
Thidiazuron® SC	1.6-6.4 oz	9.6 oz	24	5	65 F	Excellent	Excellent	Excellent	None
Ginstar®	6.4-16 oz	16 oz	12	5	60 F	Excellent	Excellent	Excellent	None

Glyphosate ³	11-44 oz	44 oz	4	7	55 F	Fair	Fair	Excellent	None
Desiccants									
Paraquat	3.1-32	32	30 min.	3	55 F	Fair	Excellent	Poor	Fair
Sodium Chlorate	4.5 # ai	N/A	24	7	55 F	Fair	Fair	Poor	None

¹Addition of spray adjuvants may enhance defoliation during cold temperatures or when leaves are tough from drought-stressed conditions. However, adjuvants may increase leaf desiccation during the early season when temperatures are warm.

²Expected rain-free periods are estimates only and may or may not be exact. Other conditions, including temperature, moisture and crop status, will play a role in product performance.

³Non-glyphosate tolerant (Roundup Ready Flex®) varieties only.
